

## Max Flow Lecture II

15-451/651

Recall the max-flow Problem:

10/13/20

Def A flow network is

- 1)  $G = (V, E)$  directed (or) oriented
  - 2) Edge capacities  $C: V \times V \rightarrow \mathbb{R}$   
st  $C(u, v) \geq 0$   
a)  $(u, v) \in E$  then  $C(u, v), C(v, u) \geq 0$  (formally)
  - 3)  $s \neq t \in V$   $s \in \text{source}$  &  $t \in \text{sink}$
- 

Def  $f: V \times V \rightarrow \mathbb{R}$  is a flow for network

G if

- 1) Capacity constraints:  $f(u, v) \leq C(u, v)$
  - 2) Skewed symmetric:  $f(u, v) = -f(v, u)$
  - 3) Flow in = Flow out for  $u \in V - \{s, t\}$   
$$\sum_{v \in V} f(u, v) = 0$$
- 

Def Netflow  $\equiv |f| = \sum_{v \in V} f(s, v)$

## The Maximum Flow Prob

2

Input: Flow-Network  $G = (V, E), s, t, c$

Output: Flow  $f$  with maximum net-flow.

---

### Residual Network

Consider Network  $G = (V, E, c)$  & flow  $f$

Def Residual Capacity:  $c_f(u, v) = c(u, v) - f(u, v)$

Residual Network:

Edges  $E_f = \{(u, v) \in V^2 \mid c_f(u, v) > 0\}$

$G_f = (V, E_f, c_f)$

Def  $P$  is an aug path if  $P$  no a path in  $G_f$   
using edges with positive capacities.

## Ford-Fulkerson Method

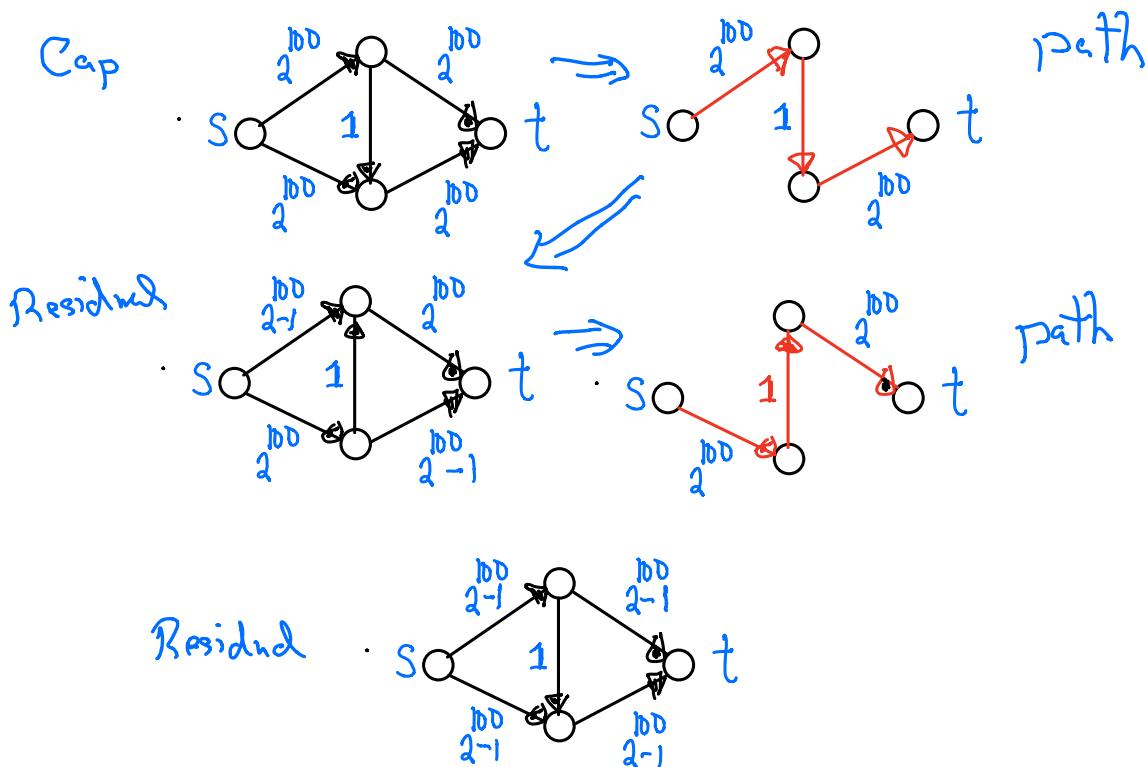

3

F-F-Method ( $G, s, t, c$ )

- 1) Initialize flow  $f$  to zero.
- 2) While  $\exists$  augmenting Path  $p$  in  $G_f$   
Set  $f_p$  be max flow on  $p$ .  
Set  $f = f_p + f$
- 3) Return  $f$ .

Issue: Of the many augmenting Path  
which one should we pick.

There are bad choices!

## Faster Max-Flow

27

- 1) The example uses 2<sup>100</sup> iteration!
- 2) For nonintegral capacities may never converge?

There are many-many ideas on better algorithms

### Types of solutions:

- 1) Find and update augmenting paths.  
But be more careful on picking paths
- 2) Drop loop invariant that  
 $\text{flow in} = \text{flow out}$
- 3) Find faster approximate flows.
- 4) Solve as a linear program

---

Today we consider only

- 1) augmenting path algorithms.

- 1) Edmonds-Karp #1 (Max Cap Paths)
- 2) Edmonds-Karp #2 (Shortest Paths)
- 3) Dinic's Alg (Blocking Flow)

## Edmonds-Karp #)

5

Alg: Pick Aug-Path with maximum capacity.  
(Max bottle-neck path)

Thm For EK#1 the number of iterations  
is at most  $m \ln(F/c)$  where  
 $F$  is max-flow &  $c$  is min capacity

We use the following claim

Claim:  $\exists$  a path of capacity  $\geq F/m$ .

Pf: By contradiction

Remove edges with cap  $< F/m$

(There will be at most  $m$ .)

These edges form a cut of size

$$F/m \cdot m < F \text{ Contradiction!}$$

□

---

After first path new max-flow  $\leq F - F/m$

$$\text{or } F(1 - 1/m)$$

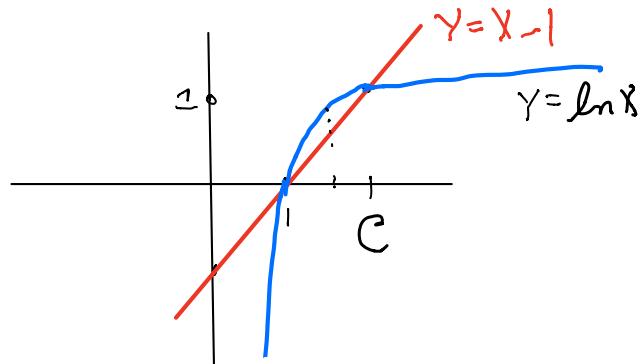

After  $i$  iterations

$$F(1 - 1/m)^i \geq c.$$

$$\text{Fact: } (1 - \frac{1}{m})^m < \frac{1}{e}$$

6

The pf follow from following diagram!

---

### Proof of thm

Goal) find an  $i$  s.t.

$$F(1 - \frac{1}{m})^b \leq c$$

iff  $((1 - \frac{1}{m})^m)^{i/m} \leq c/F$

$$\Leftarrow \left(\frac{1}{e}\right)^{i/m} \leq c/F \quad (\text{suffice})$$

iff  $F/c \leq c^{i/m}$

iff  $\ln(F/c) \leq i/m$

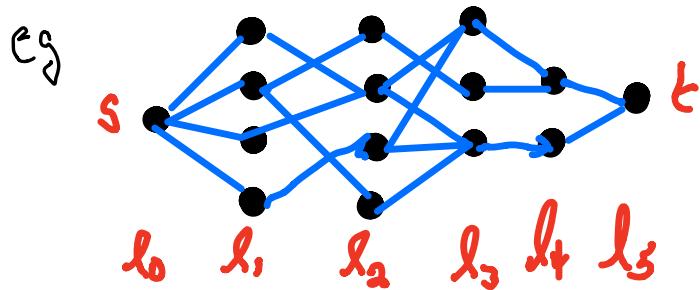

iff  $m \ln(F/c) \leq i$  works. □

## Edmonds-Karp #2

Alg: Pick Aug-Path with smallest length  
(#edges, #hops)

Def: The level graph  $L_G$  of  $G$  or  $G_f$

$$\text{level}_i = \{v \in V \mid i \text{ hops from } s\}$$

Observations about  $L_G$ :

- 1) No edge from  $l_i$  to  $l_j$   $j > i$  (Why?)
- 2) Edge from  $l_i$  to  $l_j$   $j \leq i$  OK.
- 3) More levels after  $t \in l_k$ .
- 4) Max # of levels  $\leq n$
- 5) If  $f$  is aug-path then level it can only increase  $G_f$ .
- 6) At most  $m$  aug-path that saturate an edge.

Thm EK2 is  $O(nm^2)$

8

$$\begin{array}{c} \text{pf: 1) cost per path } O(m) \\ \text{2) paths per level } m \\ \text{3) #levels } n \\ \hline \text{Total: } O(n \cdot m^2) \end{array} \quad \text{cost per level}$$

Goal: Find  $O(n \cdot m)$  cost per level Alg!

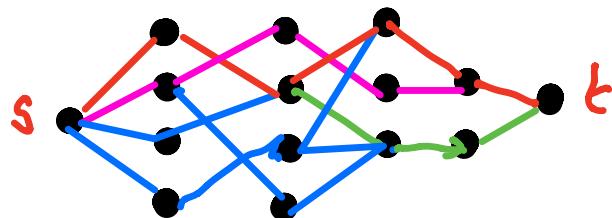

Find  $O(n^2)$  cost per level Alg!

Def: For each vertex  $v$  fix an ordering of edges out of  $v$  to next level.

Thus for each path from  $s$  to  $t$  we get a sequence of integers.

This gives a lexicographic ordering of the paths.

Dinic: Add aug-path in lexicographic order.  
Same as DFS order.

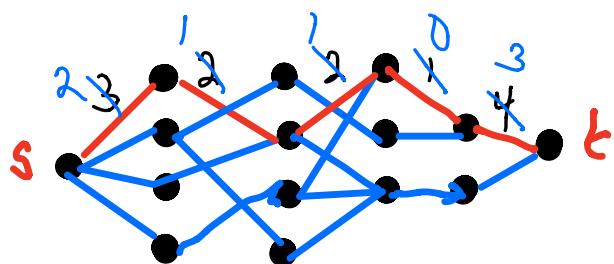

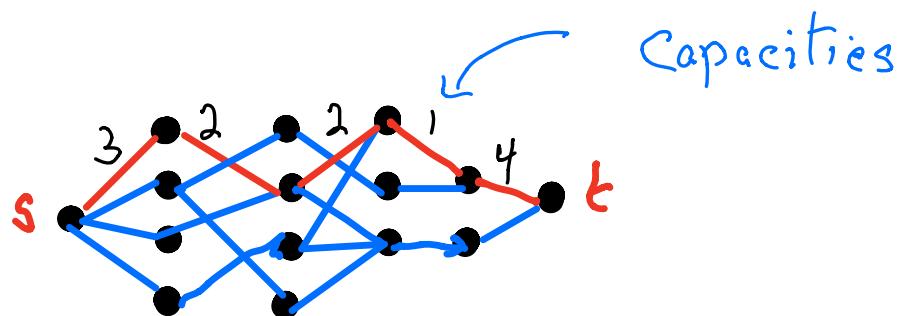

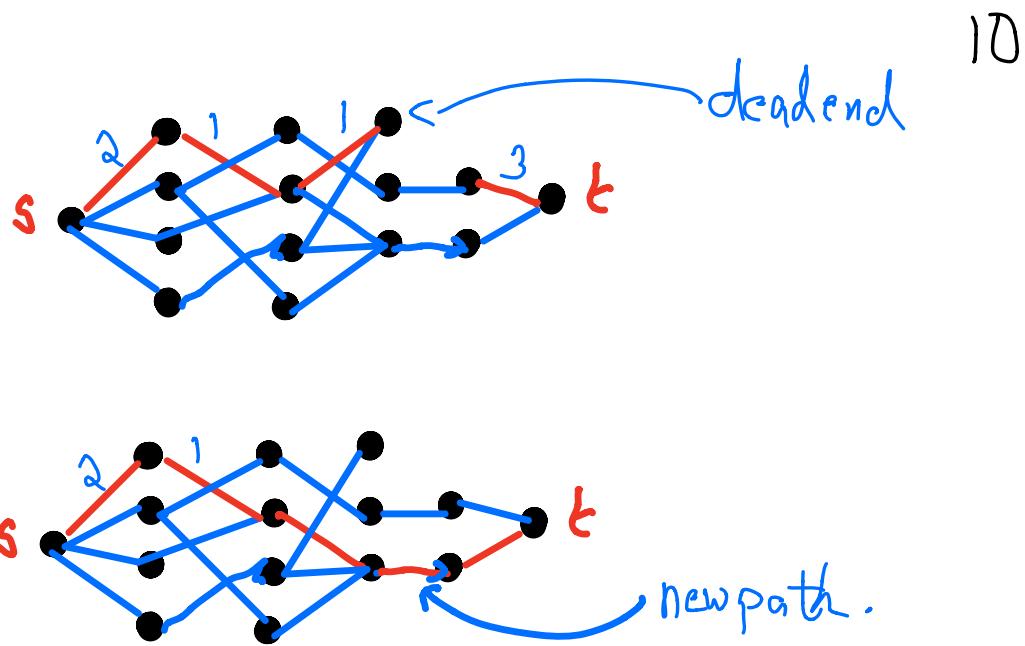

first path red  
Second green  
third violet

Dinic's Blocking Flow Alg.:

1) Find her first path from  $s$  to  $t$ .  
(Removing deadend edges)

2) Update residual graph  
(Removing saturated edges)

## Efficient Implementation

Edges are not deleted. We use pointers to keep track of "deleted" edges.

For each vertex maintains the following

Attributes:

$bottle(v)$   $\equiv$  Bottleneck on active path from  $s$  to  $v$ .

$edge(v)$   $\equiv$  Bottleneck edge. (first)

$next(v)$   $\equiv$  Next live edge out of  $v$ .

## Timing for Dinic's Blocking Flow

1)

### Observe:

- 1) An edge is traversed twice for each path found  
(Once in each direction)
- 2) An edge is traversed twice for dead ends  
(Once in each direction)  
(Edge is deleted)

### Charging Rule:

- 1) Charge type 1) to paths.
- 2) Charge type 2) to edge

### Total cost:

- 1)  $m$  paths of at most  $n$  edges
- 2)  $m$  edges

---

$$\mathcal{O}(nm + m) = \mathcal{O}(nm)$$

□

## MPM Alg for Blocking-Flow

12

Def:  $\text{Capacity}(v \in V) = \min(\text{InCap}(v), \text{OutCap}(v))$

Let  $\bar{v}$  have min Cap

---

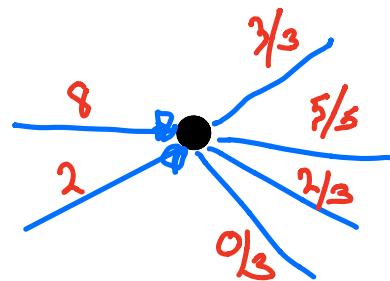

Claim:  $\exists$  flow of size  $\text{Cap}(\bar{v})$  and  
greedy alg works.

---

## MPM Alg

- 1) Find min cap vertex  $\bar{v}$  and cap  $c$ .
- 2) Lexiographically push  $c$  flow from  $\bar{v}$  to  $t$
- 3) Lexiographically pull  $c$  flow from  $\bar{v}$  to  $s$ .
- 4) Repeat while  $\text{min cap} > 0$ .

Note Always saturate an edge before using new edge.

Thm MPM Alg is  $\mathcal{O}(n^2)$  time to find Blocking-Flow. 13

Charging Rule:

- 1) If edge becomes saturated charge to edge.
- 2) If only partial flow added edge then charge node.

---

Total cost of one MPM push-pull flow is at most  
 $\# \text{saturated edges} + n$

---

Total cost of MPM blocking-flow is at most:

- 1)  $\# \text{all saturated edges} \leq m$
  - 2)  $\# \text{of push-pulls} \times n \leq n^2$
- 

Total cost  $\mathcal{O}(n^2 + m) = \mathcal{O}(n^2)$

MPM Alg is  $\mathcal{O}(n^3)$
